

How Small is Small?

Non-linearities in Heterogeneous Agent Models

Javier Bianchi¹ Greg Kaplan²

¹Federal Reserve Bank of Minneapolis

²University of Chicago, e61 Institute & NBER

Overview

- Heterogeneous-agent (HA) models have become a workhorse framework for macroeconomic analysis
 - ▶ Capture salient features of household spending and saving
 - ▶ Match the level and distribution of MPCs in the data

Overview

- Heterogeneous-agent (HA) models have become a workhorse framework for macroeconomic analysis
 - ▶ Capture salient features of household spending and saving
 - ▶ Match the level and distribution of MPCs in the data
- MPC heterogeneity is central to departures from Ricardian equivalence
 - ▶ These departures drive the aggregate effects of fiscal stimulus

Overview

- Heterogeneous-agent (HA) models have become a workhorse framework for macroeconomic analysis
 - ▶ Capture salient features of household spending and saving
 - ▶ Match the level and distribution of MPCs in the data
- MPC heterogeneity is central to departures from Ricardian equivalence
 - ▶ These departures drive the aggregate effects of fiscal stimulus
- Most of the literature uses local methods, linearizing the aggregate consumption function around steady state (SSJ, Auclert, Bardóczy, Rognlie & Straub 2021)
 - ▶ Well-understood that local methods are *accurate for small enough shocks*

Overview

 - ▶ Capture salient features of household spending and saving
 - ▶ Match the level and distribution of MPCs in the data
 - MPC heterogeneity is central to departures from Ricardian equivalence
 - ▶ These departures drive the aggregate effects of fiscal stimulus
 - Most of the literature uses local methods, linearizing the aggregate consumption function around steady state (SSJ, Auclert, Bardóczy, Rognlie & Straub 2021)
 - ▶ Well-understood that local methods are *accurate for small enough shocks*
- BUT: How small is small?
 - Our answer: for fiscal transfers, “small” must be *very small*.

Overview (ctd)

- In calibrated HA models, MPCs are highly non-linear in wealth
 - ▶ MPCs fall sharply away from borrowing constraints

Overview (ctd)

- In calibrated HA models, MPCs are highly non-linear in wealth
 - ▶ MPCs fall sharply away from borrowing constraints
- Transfers move households out of high-MPC regions
 - ▶ Aggregate consumption response is concave in the size of transfers
 - ▶ Linear methods substantially overstate response to fiscal stimulus for small shocks

Overview (ctd)

- In calibrated HA models, MPCs are highly non-linear in wealth
 - ▶ MPCs fall sharply away from borrowing constraints
- Transfers move households out of high-MPC regions
 - ▶ Aggregate consumption response is concave in the size of transfers
 - ▶ Linear methods substantially overstate response to fiscal stimulus for small shocks
- Higher-order local methods do not fix the problem
 - ▶ At the borrowing constraint, consumption is locally linear; MPC shifts discretely once constraint becomes slack.

Overview (ctd)

- In calibrated HA models, MPCs are highly non-linear in wealth
 - ▶ MPCs fall sharply away from borrowing constraints
 - Transfers move households out of high-MPC regions
 - ▶ Aggregate consumption response is concave in the size of transfers
 - ▶ Linear methods substantially overstate response to fiscal stimulus for small shocks
 - Higher-order local methods do not fix the problem
 - ▶ At the borrowing constraint, consumption is locally linear; MPC shifts discretely once constraint becomes slack.
- Local methods are unreliable when a failure of Ricardian equivalence from high MPCs drives aggregate responses
 - ▶ Shocks where they *are* accurate are those where $HA \approx RA$.

Roadmap

1. Partial equilibrium model and calibration
2. Fiscal stimulus in general equilibrium
3. Other shocks

Environment: Household Problem

Given an interest rate r and a path of transfers $\{T_t\}$, a household solves

$$\max_{\{c_{i,t}, a_{i,t}\}} \mathbb{E}_0 \sum_{t=0}^{\infty} \beta_i^t u(c_{i,t})$$

subject to

$$c_{i,t} + a_{i,t} \leq (1+r)a_{i,t-1} + (1-\tau)y_{i,t} + T_t \quad \text{and} \quad a_{i,t} \geq 0.$$

Intertemporal Euler equation:

$$u'(c_{i,t}) \geq \beta_i(1+r)\mathbb{E}_t u'(c_{i,t+1})$$

with equality if $a_{i,t} > 0$.

Environment: Household Problem

Given an interest rate r and a path of transfers $\{T_t\}$, a household solves

$$\max_{\{c_{i,t}, a_{i,t}\}} \mathbb{E}_0 \sum_{t=0}^{\infty} \beta_i^t u(c_{i,t})$$

subject to

$$c_{i,t} + a_{i,t} \leq (1+r)a_{i,t-1} + (1-\tau)y_{i,t} + T_t \quad \text{and} \quad a_{i,t} \geq 0.$$

Intertemporal Euler equation:

$$u'(c_{i,t}) \geq \beta_i(1+r)\mathbb{E}_t u'(c_{i,t+1})$$

with equality if $a_{i,t} > 0$.

Aggregate consumption function:

$$C_t(\{T_s\}) = \int c_t(a, y, \beta) d\Gamma_t(a, y, \beta)$$

Fiscal Transfers

Starting from steady state, a one-time lump-sum transfer at $t = 0$:

$$T_0 = T + \Delta, \quad T_t = T \text{ for } t > 0.$$

Fiscal Transfers

Starting from steady state, a one-time lump-sum transfer at $t = 0$:

$$T_0 = T + \Delta, \quad T_t = T \text{ for } t > 0.$$

Object of interest. Aggregate consumption response:

$$C_t(\Delta) - C_t(0)$$

Fiscal Transfers

Starting from steady state, a one-time lump-sum transfer at $t = 0$:

$$T_0 = T + \Delta, \quad T_t = T \text{ for } t > 0.$$

Object of interest. Aggregate consumption response:

$$\mathcal{C}_t(\Delta) - \mathcal{C}_t(0)$$

Non-linear solution

- Solve individual household problem exactly and aggregate

Linear solution

- Taylor expansion of aggregate consumption function around steady state

$$\mathcal{C}_t^{\text{lin}}(\Delta) = \mathcal{C}_t(0) + \Delta \cdot \left. \frac{\partial \mathcal{C}_t}{\partial \Delta} \right|_{\Delta=0}$$

Fiscal Transfers

Starting from steady state, a one-time lump-sum transfer at $t = 0$:

$$T_0 = T + \Delta, \quad T_t = T \text{ for } t > 0.$$

Object of interest. Aggregate consumption response:

$$\mathcal{C}_t(\Delta) - \mathcal{C}_t(0)$$

Non-linear solution

- Solve individual household problem exactly and aggregate

Linear solution

- Taylor expansion of aggregate consumption function around steady state

$$\mathcal{C}_t^{\text{lin}}(\Delta) = \mathcal{C}_t(0) + \Delta \cdot \left. \frac{\partial \mathcal{C}_t}{\partial \Delta} \right|_{\Delta=0}$$

Calibration

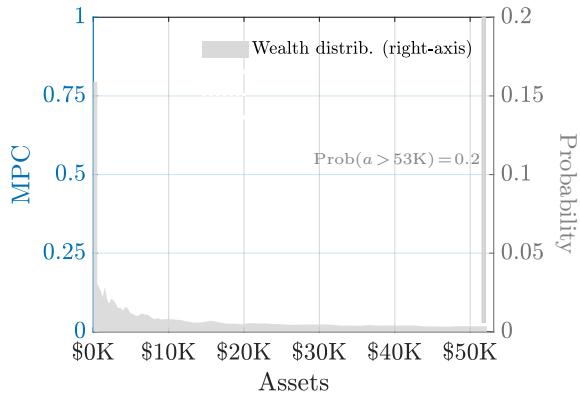

- A period = a quarter. Annual GDP per household $\approx$ \$166K. Normalize average quarterly income to 1.
- Earnings process, $y_{i,t}$, subject to temporary and persistent shocks
 - ▶ Calibrated as in Kaplan-Violante (2022) to match distribution of households' earnings
- Interest rate 2% annual.
- Tax rate (τ) = 27.4%
- Steady-state transfers = 15% of GDP ($\approx$ \$25K/yr)

Calibrated to match moments

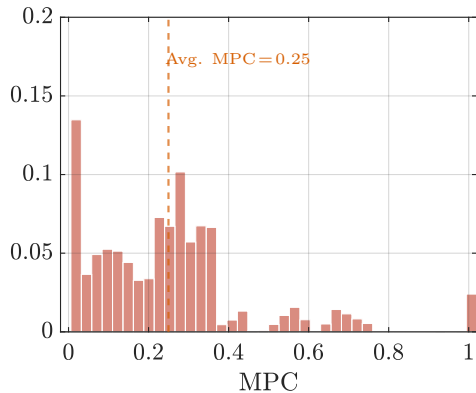

$$\left. \begin{array}{l} \text{Mean wealth / annual GDP} = 100\% (\approx \$166\text{K}) \\ \text{Avg. quarterly MPC (out of \$1,000)} = 25\% \end{array} \right\} \Rightarrow \bar{\beta} = 0.972, \sigma_{\beta} = 0.010$$

Steady-state wealth distribution and MPCs

Steady-state wealth distribution and MPCs

(a) Wealth distribution

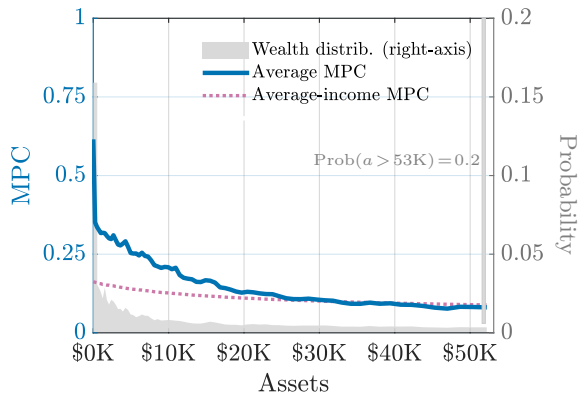

(b) MPC distribution

Aggregate consumption response

Aggregate consumption response

Aggregate consumption response

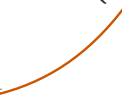

Linear **substantially overstates** response:

- At $\Delta = 5\%$ of annual GDP ($\approx \$8,300$): **overstates by 42%**
- Even at $\Delta = 0.5\%$: **overstates by 17%**

Concavity of Aggregate Consumption Function

- MPC is decreasing in wealth and **drops discontinuously** at the kink

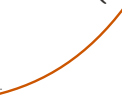

$$m(x, y) = \begin{cases} 1, & x < \bar{x}(y), \\ m^+ & x > \bar{x}(y). \end{cases}$$

$$\frac{\beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}{u''(c) + \beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}$$

Concavity of Aggregate Consumption Function

- MPC is decreasing in wealth and **drops discontinuously** at the kink

$$m(x, y) = \begin{cases} 1, & x < \bar{x}(y), \\ m^+ & x > \bar{x}(y). \end{cases}$$

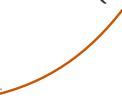

$$\frac{\beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}{u''(c) + \beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}$$

- Non-linear: transfer may move constrained households **off the constraint**: their MPC drops from 1 to m^+

Concavity of Aggregate Consumption Function

- MPC is decreasing in wealth and **drops discontinuously** at the kink

$$m(x, y) = \begin{cases} 1, & x < \bar{x}(y), \\ m^+ & x > \bar{x}(y). \end{cases}$$

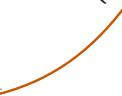

$$\frac{\beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}{u''(c) + \beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}$$

- Non-linear: transfer may move constrained households **off the constraint**: their MPC drops from 1 to m^+
- Linear methods effectively treat steady-state constrained households as hand-to-mouth (i.e., as if $\text{MPC} = 1$ permanently, regardless of size of transfers)

Concavity of Aggregate Consumption Function

- MPC is decreasing in wealth and **drops discontinuously** at the kink

$$m(x, y) = \begin{cases} 1, & x < \bar{x}(y), \\ m^+ & x > \bar{x}(y). \end{cases}$$

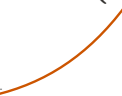

$$\frac{\beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}{u''(c) + \beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}$$

- Non-linear: transfer may move constrained households **off the constraint**: their MPC drops from 1 to m^+
- Linear methods effectively treat steady-state constrained households as hand-to-mouth (i.e., as if $\text{MPC} = 1$ permanently, regardless of size of transfers)

Concavity of Aggregate Consumption Function

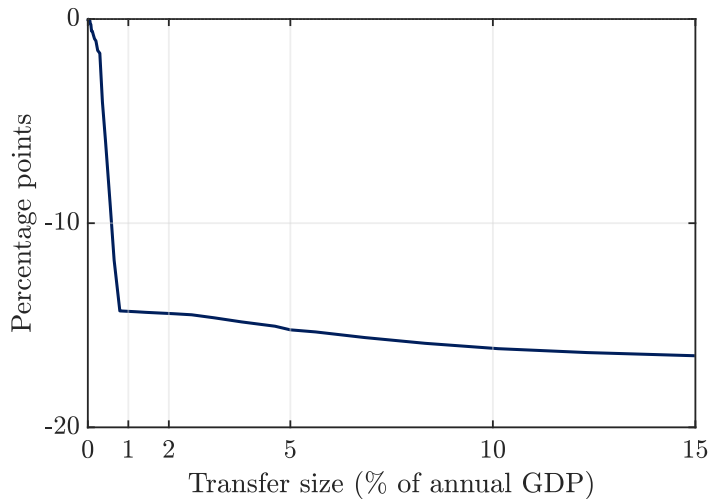

- MPC is decreasing in wealth and **drops discontinuously** at the kink

$$m(x, y) = \begin{cases} 1, & x < \bar{x}(y), \\ m^+ & x > \bar{x}(y). \end{cases}$$

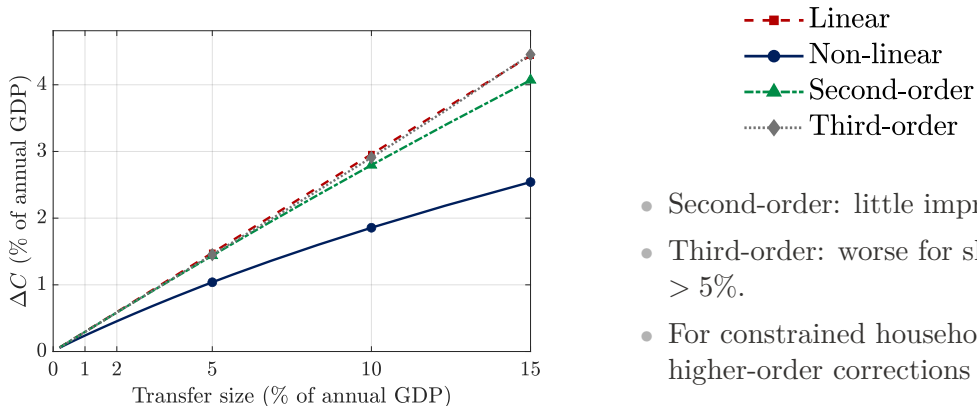

$$\frac{\beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}{u''(c) + \beta \mathbb{E}[V_{aa}(a'(x, y), y') \mid y]}$$

- Non-linear: transfer may move constrained households **off the constraint**: their MPC drops from 1 to m^+
- Linear methods effectively treats steady-state constrained households as hand-to-mouth (i.e., as if $\text{MPC} = 1$ permanently, regardless of size of transfers)
- Aggregate MPC $\downarrow$ as $\Delta \uparrow \Rightarrow$ **concave** aggregate consumption response

Change in share of constrained households

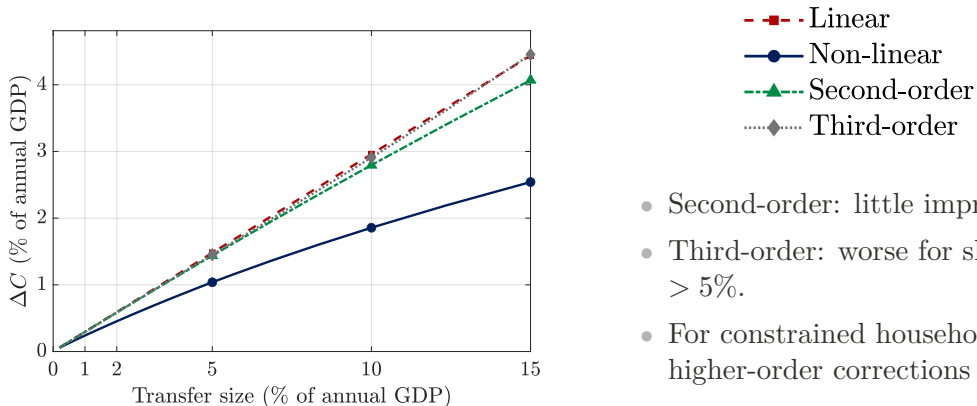

Higher-order approximations

- Second-order: little improvement
- Third-order: worse for shocks $> 5\%$.
- For constrained households: higher-order corrections are zero

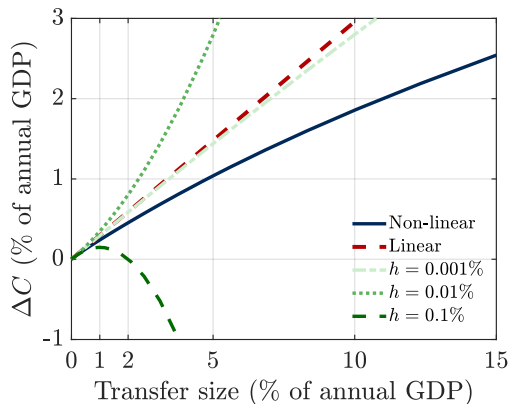

Higher-order approximations

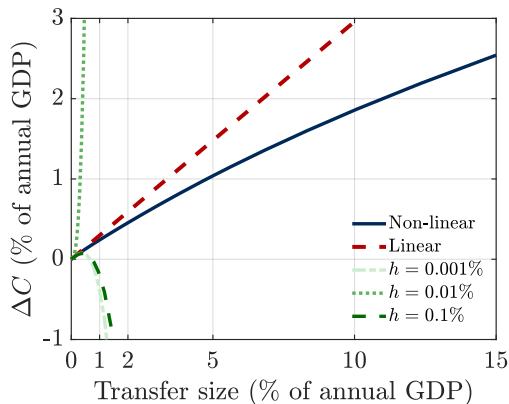

- Second-order: little improvement
- Third-order: worse for shocks $> 5\%$.
- For constrained households: higher-order corrections are zero

Higher-order with finite differences

(a) Second order

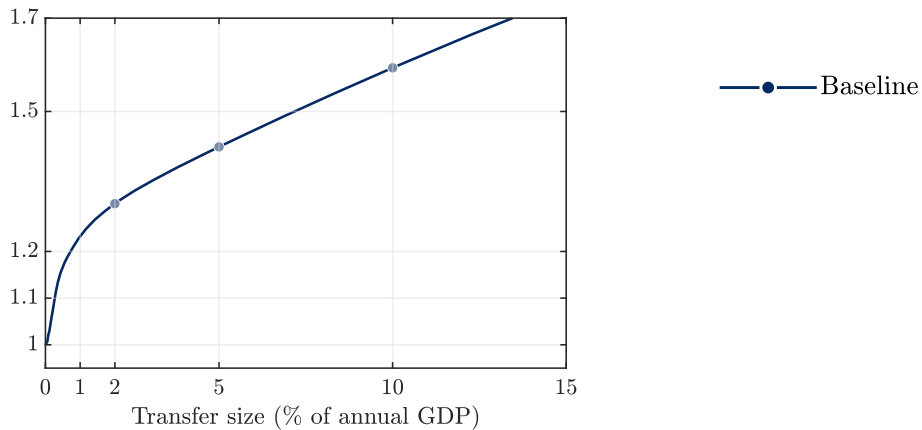

(b) Third order

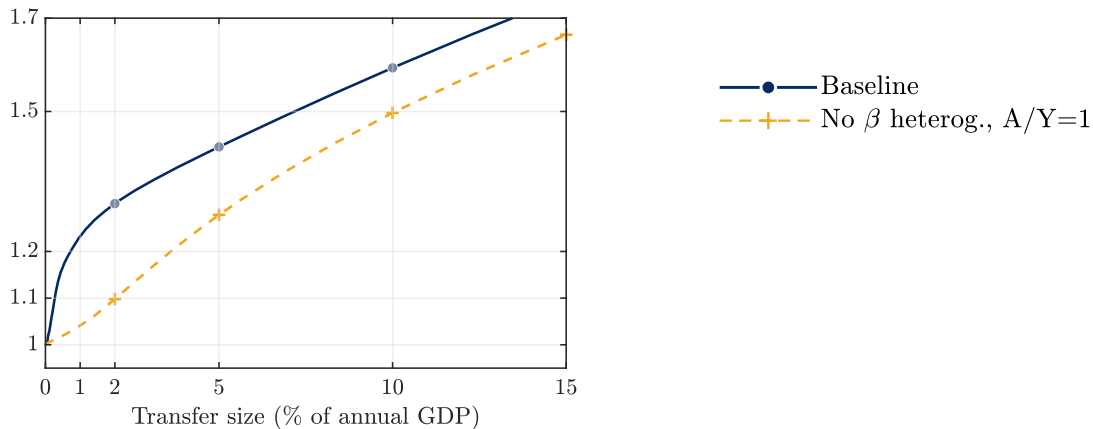

Extremely sensitive to step size and poorly behaved even for small shocks.

Roadmap

1. Partial equilibrium model and calibration
2. Fiscal stimulus in general equilibrium
3. Other shocks

General Equilibrium Model

PE + production, labor supply, nominal rigidities, fiscal/monetary rules.

General Equilibrium Model

- **Households:**

- ▶ Utility flow, $u(c_{it}) - v(n_{it})$ with $v' > 0, v'' > 0$
- ▶ Income $(1 - \tau) \frac{W_t}{P_t} e_{it} n_{it} + d_{i,t}$

General Equilibrium Model

- **Households:**

- ▶ Utility flow, $u(c_{it}) - v(n_{it})$ with $v' > 0, v'' > 0$
- ▶ Income $(1 - \tau) \frac{W_t}{P_t} e_{it} n_{it} + d_{i,t}$
- ▶ Labor union with sticky wages (linearized)

$$\pi_t = \kappa \left(v'(N_t) - \frac{1 - \tau}{C_t} \right) + \bar{\beta} \pi_{t+1}, \quad (\text{Phillips Curve})$$

General Equilibrium Model

- **Households:**

- ▶ Utility flow, $u(c_{it}) - v(n_{it})$ with $v' > 0, v'' > 0$
- ▶ Income $(1 - \tau) \frac{W_t}{P_t} e_{it} n_{it} + d_{i,t}$
- ▶ Labor union with sticky wages (linearized)

$$\pi_t = \kappa \left(v'(N_t) - \frac{1 - \tau}{C_t} \right) + \bar{\beta} \pi_{t+1}, \quad (\text{Phillips Curve})$$

- **Firms and Technology:**

$$\left. \begin{array}{l} \text{Production: } Y_t = N_t \\ \text{Flexible prices} \end{array} \right\} \Rightarrow W_t = P_t, \quad d_{i,t} = 0$$

General Equilibrium Model

Government Policies

General Equilibrium Model

Government Policies

- Government budget:

$$B_t + \tau Y_t = G + T_t + (1 + r_{t-1})B_{t-1}$$

- Fiscal rule

$$T_t = T - \phi_B \bar{r}(B_{t-1} - \bar{B})$$

- Monetary policy:

$$i_t = \bar{i} + \phi_\pi(\pi_t - \bar{\pi})$$

Will examine alternative versions

Calibration

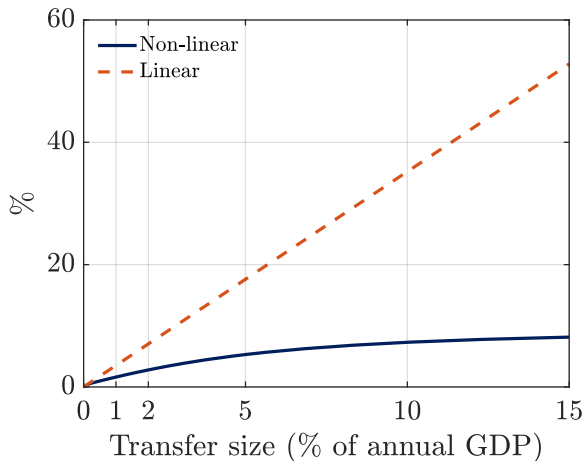

Parameter	Value	Description
$\bar{B}$	4	Steady-state government debt=100% GDP
$\bar{r}$	0.02	Steady-state annual real interest rate
$\bar{\pi}$	0	Steady-state inflation
κ	0.01	Phillips curve slope
ν	1	Frisch elasticity of labor supply
ϕ_{π}	1.5	Taylor coefficient
ϕ_B	8	Fiscal rule
G	0.104	Government spending
T	0.15	Government Transfers

Computation:

- Linear: sequence space Jacobian (ABRS)
- Non-linear: quasi-Newton algorithm

Flexible-Price Allocation: Real Interest Rate

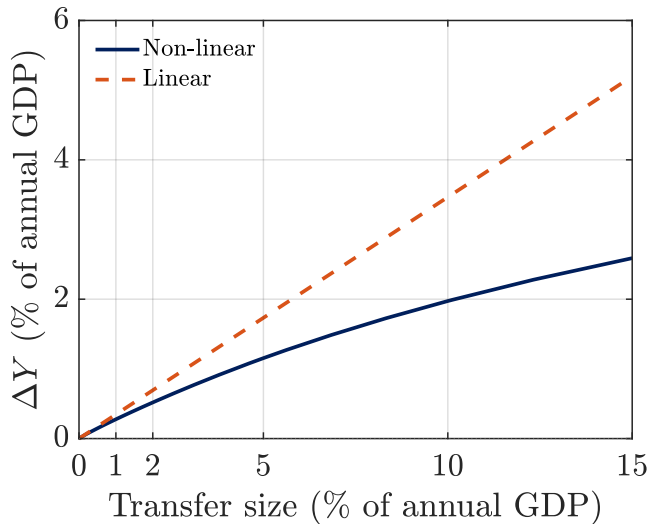

Real rate response

- No output effects
- Constrained households with high MPCs raise consumption
- Linear solution again overstate increase in demand and the rise in r

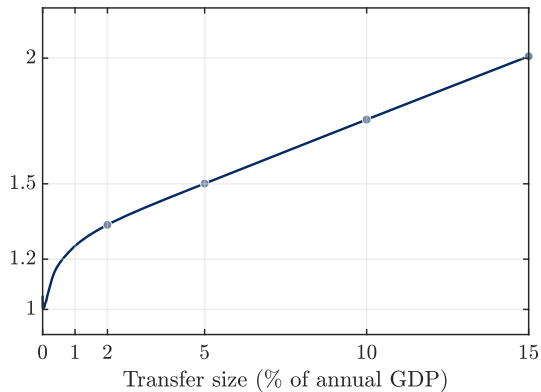

With household labor choice →

HANK: Output Response

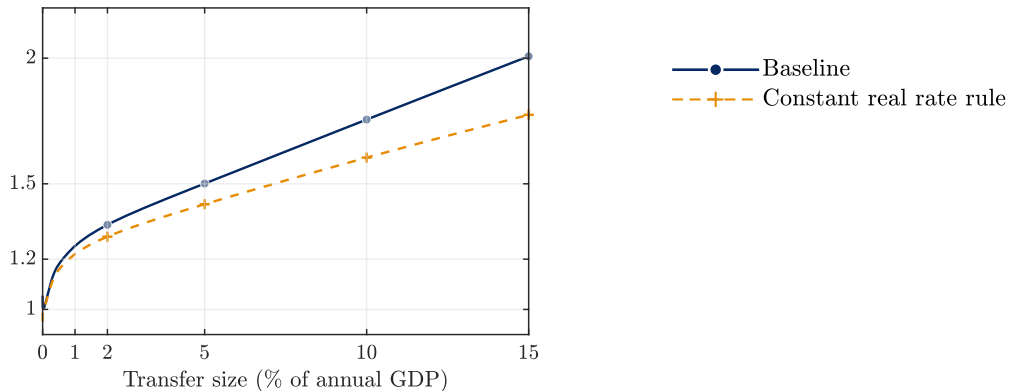

- At $\Delta = 2\%$ GDP: linear overstates by 34%
- At $\Delta = 5\%$ GDP: linear overstates by 50%

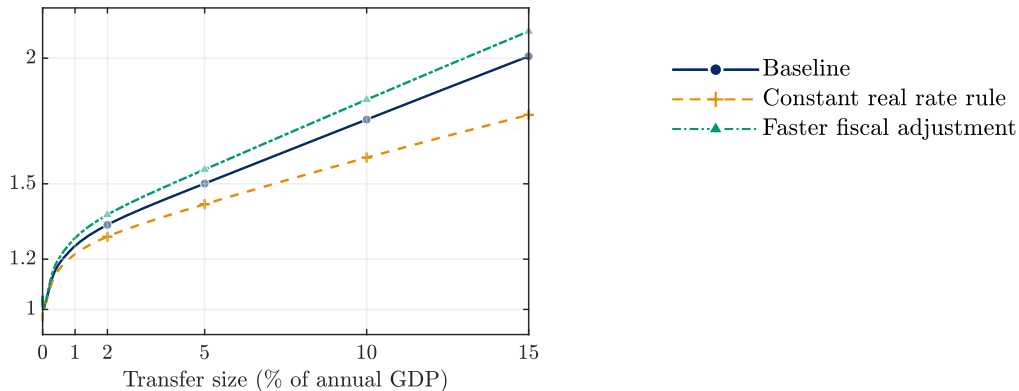

Sensitivity in HANK: Linear / Non-Linear

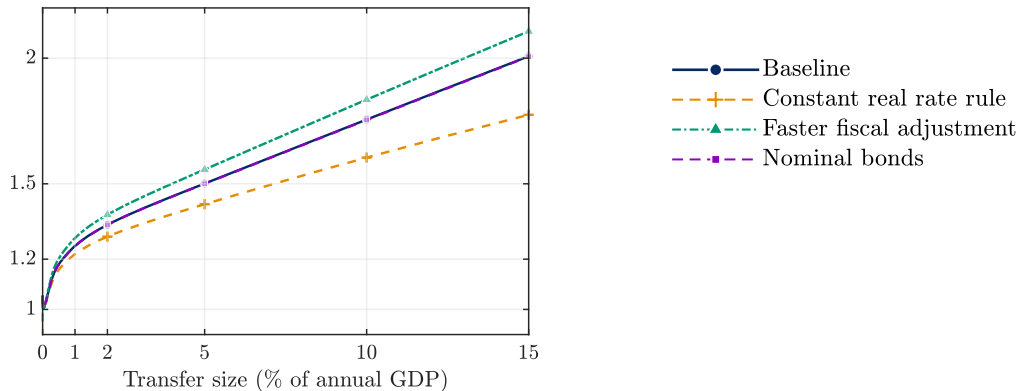

Sensitivity in HANK: Linear / Non-Linear

For fiscal transfers, “small” must be *very small*.

Appendix

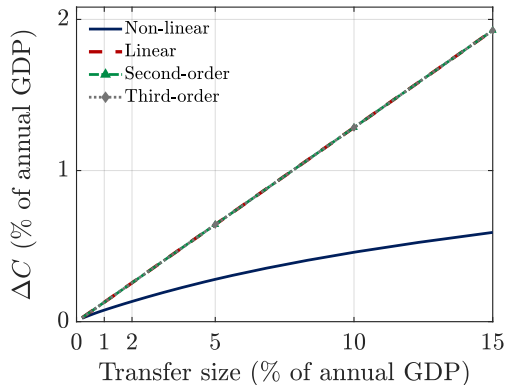

Additional figures

Implied parameters

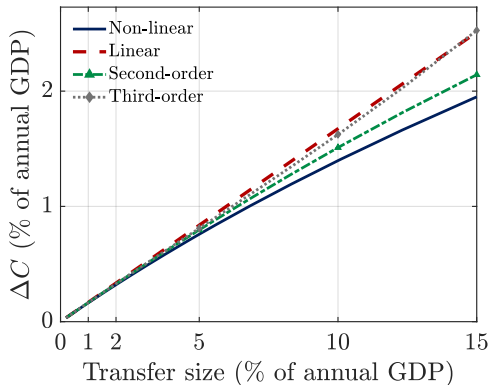

Parameter	Value
<i>Preferences & assets</i>	
r (annual)	2%
$\bar{\beta}$ (mean disc. factor)	0.972
σ_{β} (dispersion)	0.010
<i>Stochastic income process (Kaplan–Violante 2022)</i>	
ϕ_z (AR persistence)	0.988
σ_{η}^2 (perm. var.)	0.044
σ_{ε}^2 (trans. var.)	0.638
λ (shock arrival)	1/4 per qtr

Constrained vs. Unconstrained

Initially constrained

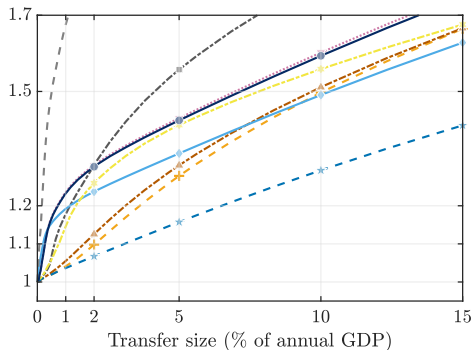

Initially unconstrained

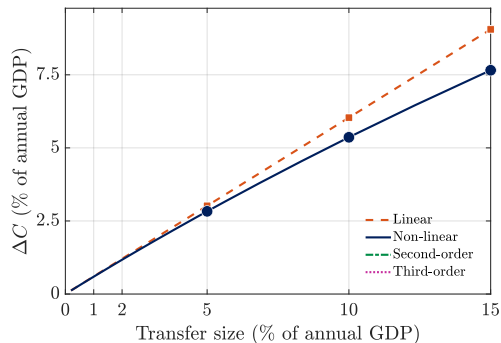

Note: Consumption response within each group, as a % of annual GDP per capita.

PE: KMV calibration and first-year response

(a) KMV calibration

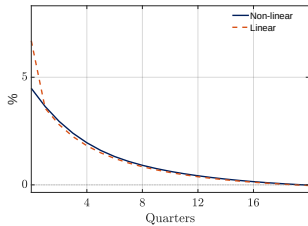

(b) First-year response

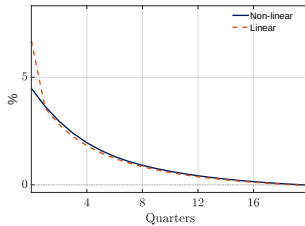

Note: Concavity is robust to the (Kaplan, Moll & Violante 2018) calibration and remains over the first year (panel b), though smaller than on impact.

GE baseline: impulse responses

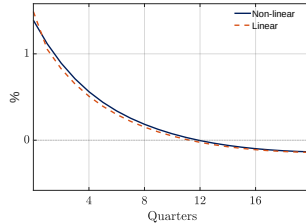

Output

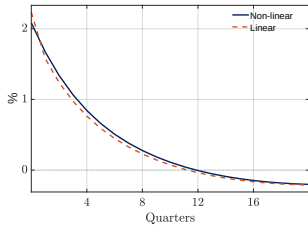

Consumption

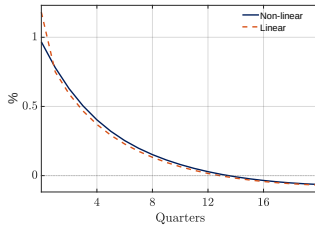

Inflation

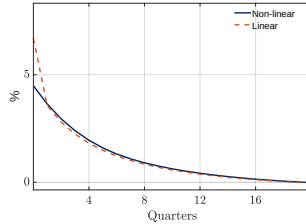

Nominal rate

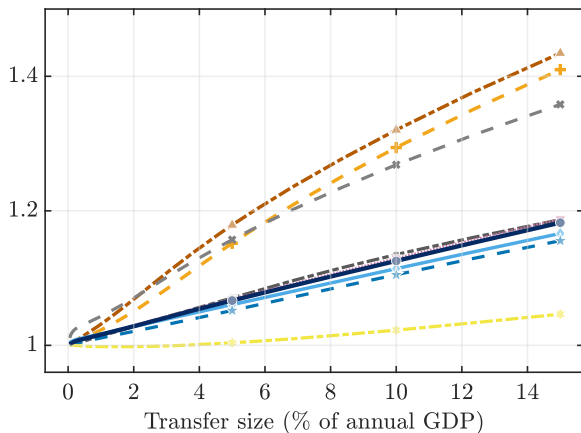

Real rate

Labor

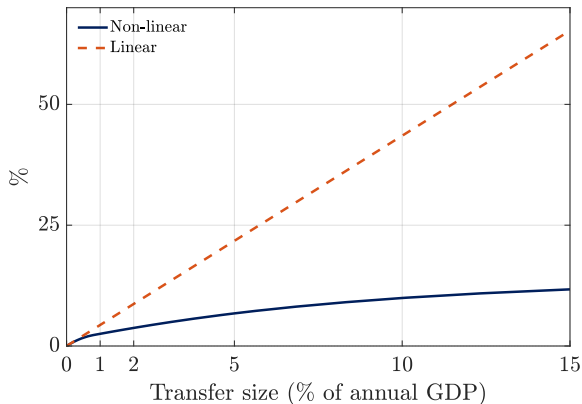

GE: first-year linear-to-non-linear ratio

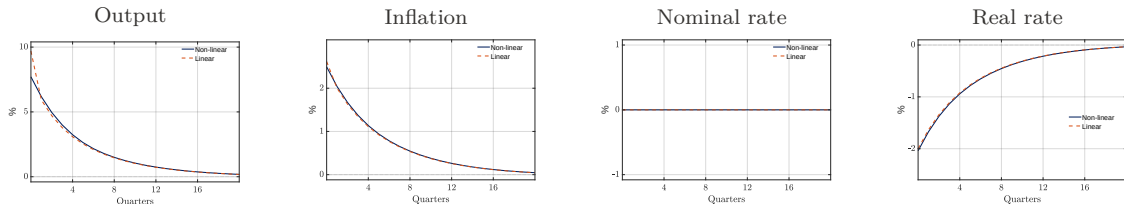

Note: Over the first year the linear method still overstates the output response, though by less than on impact.

GE: flexible prices with household labor choice

- Households choose labor freely (no union)
- Small output effects via labor-supply incentives
- Real-rate response remains **concave** in Δ — same mechanism as the union case

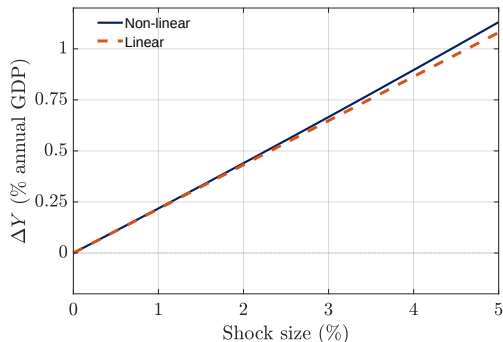

GE: unfunded stimulus (FTPL) impulse responses

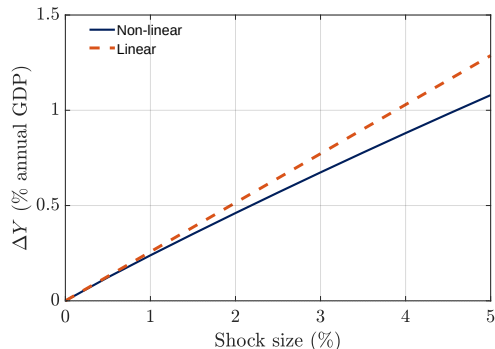

Note: Under the FTPL (active fiscal, passive money), the output effect does not hinge on a failure of Ricardian equivalence, so non-linearity is much milder.

Other shocks: discount factor and labor tax

(a) Discount-factor shock

(b) Labor-tax cut

Note: Both generate **milder non-linearity** than lump-sum transfers; a τ cut shifts fewer resources to low-income, constrained households.
